**Introduction**

Haloclines and thermoclines are foundational to the dynamics of estuarine environments. These factors influence the estuary both biotically and abiotically, and they are in turn influenced by the tides. The Snohomish River, which flows into Possession Sound, is significantly influenced by tidal cycles, though the full scope of these influences has not yet been thoroughly investigated by ORCA students. This study will investigate the connections between current speeds at the mouth of the Snohomish River and temperatures. A previous study of the author’s suggests that current speeds are inversely correlated with thermocline stratification, but this research lacks scope and statistical support. This study aims to expand both the hypotheses posed previously and their support by increasing sample size and statistical analysis.

**Study Site**

**Methods**

Temperature data used in this study were collected by ORCA’s Conductivity, Temperature, and Depth sensor (CTD). Current speed data were collected by ORCA's Acoustic Doppler Current Profiler (ADCP). Both sensors were within close proximity of each other as indicated by Figure 1. The CTD was moored to the Everett Marina dock and the ADCP was secured to the riverbed. The data used in this study was collected between July 25th and September 10th of 2019. These data were selected specifically for their convenience; this time frame saw the longest consecutive coincidence of ADCP and CTD readings.

**Results**

![Figure 2](image)

Figure 2: A time-series heatmap of current speeds captured by the Everett Marina ADCP from July 25th to September 10th. The height axis indicates the maximum number of cells detected by the ADCP, with each cell representing two meters of water. When only the first cell is colored, the water is two meters deep above the ADCP and vice versa.

**Conclusions**

![Figure 3](image)

Figure 3: A 2019 time-series graph of temperatures 2 meters below the surface and tide heights from July 25th to September 10th. Temperature readings were taken from the Everett Marina CTD indicated in Figure 1. Tide data courtesy of NOAA.

![Figure 4](image)

Figure 4: A scatter plot of current speeds in the first cell versus temperature. The line of best fit is indicated in blue. In support of a linear correlation: $r = 0.1525; p < 0.001$.

**ORCA**

The Ocean Research College Academy is a dual enrollment program where high school juniors and seniors experience innovative, interdisciplinary and student-centered learning. A longitudinal study of the local estuary forms the backbone of the first-year experience, and leads students to conduct independent research in their second year of the program. ORCA has received grants for a research lab, research vessel, and summer research funded by the National Science Foundation.
